

Electricity market sukhum

An electricity market is a system that enables the exchange of electrical energy, through an electrical grid.¹; Historically, electricity has been primarily sold by companies that operate electric generators, and purchased by consumers or electricity retailers.

The electric power industry began in the late 19th century in the United States and United Kingdom. Throughout the 20th century, and up to the present, there have been deep changes in the economic management of electricity. Changes have occurred across different regions and countries, for many reasons, ranging from technological advances (on supply and demand sides) to politics and ideology.

In recent years, governments have reformed electricity markets to improve management of variable renewable energy and reduce greenhouse gas emissions.⁵;⁶;

The structure of an electricity market is quite complex.⁷; Markets often include mechanisms to manage a variety of relevant services alongside energy. Services may include:

A simple "energy-only" wholesale electricity market would only facilitate the sale of energy, without regard for other services that may support the system, and experienced problems once implemented alone. To account for this, the electricity market structure typically includes:⁷;

The competitive retail electricity markets were able to maintain their simple structure.⁷;

In addition, for most major operators, there are markets for transmission rights[;]citation needed[;] and electricity derivatives such as electricity futures and options, which are actively traded.

The market externality of greenhouse gas emissions is sometimes dealt with by carbon pricing.¹¹;

Electricity market is characterized by unique features¹²;

 that are atypical in the markets for commodities or consumption goods.

There are many other physical and economic constraints affecting the electricity network and the market, with some creating non-convexity:¹⁸;

Electricity networks are natural monopolies, because it is not feasible to build multiple networks competing against one another. In order to address this, many electricity networks are regulated to address the risk of price gouging. The two main types of network price regulation are:¹⁹;

The design of transmission network limits the amount of electricity that can be transmitted from one

tightly-coupled area ("node") to another, so a generator in one node might be unable to service a load in another node (due to "transmission congestion"), potentially creating fragments of the market that have to be served with local generation ("load pockets").
