

## Wind turbine for home netherlands

The Dutch have a reputation for obtaining energy by means of a windmill. This energy was used for all kinds of purposes, such as milling of raw material, water pumping, etc .. Today, the windmill is a means to generate sustainable energy.

The Dutch MSc Marinus Mieremet has been working since 2003 on a new and more efficient way of generating power by a wind turbine.

The Archimedes windmill is a new type of wind turbine comprising three circular blades which are wrapped around one another and then expanded. This creates a three-dimensional conical turbine, similar to elongated shells found on the beach. The special design ensures that wind is drawn into the turbine. The average yield is many times higher compared to a normal urban windmill propeller.

With the growing emphasis on sustainable energy solutions, the Dutch company introduces modern-day wind technology, in the form of the Liam F1 Urban Wind Turbine. With this new technology, it is set to change how homes and businesses leverage wind energy. Compact, effective, and noiseless, Liam F1 produces a more environmentally friendly alternative to regular turbines. But what really makes this windmill so different, and what makes it such a hot topic all over the world?

Liam F1 Urban Wind Turbine comprises a design engineered for urban areas, unlike other conventional wind turbines that are ineffective in most of these areas because they are turbulent. The design was inspired by nature and the theories of Archimedes; in fact, they are screw-shaped designs having an impressive energy density of up to 80% which is quite impressive compared with the actual 25% energy density of conventional turbines.

With a wind speed of 5 m/s, this unit can produce 1,500 kWh in a year, which is enough to supply energy to an average European household about half the year. These units are small enough to fit beautifully on rooftops and walls without the need for bulky poles or towers.

Its low cut-in wind speed of 2 m/s ensures good performance profile under variable winds in urban areas. Staying true to its promises, it is almost perfectly silent operationally unlike most standard wind turbines making it very conducive for residential settings where issues of noise pollution are paramount.

It is also adaptable in its internal systems to be used in a town atmosphere. It comes in different colors, so it

can fit into any existing architecture. Because it's made to yaw naturally with the wind, complicated mechanical systems are not required, which basically means the innovation can be further enhanced in terms of its efficiency and reliability.

For efficient energy production, Liams can also be coupled with solar panels. This hybrid system would produce very consistent energy supply, offsetting intermittency from sunshine or wind. Mini-Liam is also a smaller version for those who cannot afford the larger space. It provides around 40% energy of its larger version.

At first glance, it seems like a very powerful flywheel system-independent system-the very rare feature, where the multiple Liams are arranged in a unique triangular alignment that permits every turbine to draw wind independently without interference from others. Not only this, but this will also enhance efficiency and create a scalable installation for higher energy demand.
