Wind turbine inverter function

Wind turbine inverter function

An essential component in off-grid wind power systems is the inverter.

The primary function of the inverter is to convert the DC (direct current) electricity produced by the turbine into AC (alternating current) electricity that can be utilized and distributed within the grid.

By optimizing the performance of an inverter, energy yield from the wind turbine can be increased, resulting in a more cost-effective system overall.

As technology advances, modern inverters offer features such as maximum power point tracking (MPPT) which ensures that the wind turbine operates at its most efficient point at all times and grid connection capabilities for seamless integration with mains electricity when available.

The inverter converts the direct current (DC) power generated by the wind turbine into alternating current (AC) power that can be used to power home appliances or sold to the grid.

However, most home appliances and the electrical grid operate on alternating current (AC) power.

To make the DC power produced by the wind turbine usable in these systems, the electricity must be converted to AC power using an inverter.

This process involves a series of complex electrical interactions, including rectification, filtering, and switching, which are controlled by advanced digital algorithms to ensure efficient and accurate power conversion.

The result is a high-quality AC power output that is indistinguishable from traditional grid power, allowing wind energy to seamlessly integrate with the grid and support a more sustainable energy future.

Many inverters in off-grid wind power systems come with grid tie capabilities, allowing excess energy to be sold back to the grid and credited to the system owner's account.

When an off-grid wind power system is equipped with a grid tie capability, it allows the system owner to sell any excess energy produced by the system back to the grid.

This is particularly useful during periods of high wind speeds or other optimal conditions where the system is producing more energy than the owner can use.
